

1. Workflow Architecture & Protection

Strategy Recommendation: Trunk-Based Development

To support our fast-moving startup, we are adopting Trunk-Based Development instead of GitFlow.

Why this is better for our team:

GitFlow involves maintaining long-lived branches (like ``develop`` and ``release``), which slows down integration and often leads to complex merge conflicts. With Trunk-Based Development, developers work on short-lived feature branches and merge them into ``main`` frequently. This keeps our codebase integrated, shortens feedback loops, and allows us to ship features to production much faster.

GitHub Branch Protection Rules for ``main``

To prevent bad or unstable code from breaking our production environment, we will enforce the following rules on the ``main`` branch:

1. Require a pull request before merging:

Direct pushes to ``main`` are blocked. All code must come through a Pull Request (PR) and receive at least 1 approving review from a teammate.

2. Require status checks to pass before merging:

The PR cannot be merged until our automated CI pipeline tests pass successfully.
